ITERATIVE EXERGEOECONOMIC OPTIMIZATION OF A COGENERATION SYSTEM

C. IONITA¹  M. MARINESCU¹  A. DOBROVICESCU¹  D. STANCIU¹

Abstract: The paper presents the exergoeconomic optimization of a simple cogeneration system composed of a gas turbine and a heat recovery generator. The iterative method for cost minimization is based on the exergy concept and the exergoeconomic variables.

Keywords: cogeneration, exergoeconomics, exergoeconomic variables

1. Introduction

The exergoeconomic optimization offers a coherent strategy, in continuous connection with the physical reality, for the search of the optimum solution. Besides the opportunity of finding the optimum solution, the exergoeconomic method also offers information about possibilities to continue the optimization procedure by the change of the system structure. The iterative technique of optimization requires minimum of available data (exergoeconomic variables) and offers information for the thermal systems optimization when other optimization procedures cannot be applied.

2. Exergoeconomic Variables

To identify the energetic efficiency and other variables is necessary to find out the Product (P) and the Fuel (F) for each analyzed thermodynamic system. The Product represents the net desired result produced in the system, and the Fuel represents the net resources which were spent to generate the product. Both Product and Fuel are measured in exergetic units. The variables considered in the exergoeconomic optimization procedure are ([1], [3]):

a) Exergetic efficiency of component k

\[ \varepsilon_k = \frac{\dot{E}_{P,k}}{\dot{E}_{Cb,k}} = 1 - \frac{\dot{E}_{D,k}}{\dot{E}_{Cb,k}} \] (1)

b) Exergy destruction rate \( \dot{E}_{D,k} \) and exergy loss rate \( \dot{E}_{L,k} \)

The connection between Fuel, Product, Exergy destruction and Exergy loss in the k subsystem is given by the relationship:

\[ \dot{E}_{P,k} = \dot{E}_{Cb,k} + \dot{E}_{D,k} + \dot{E}_{L,k} \] (2)

c) Exergy destruction related to the fuel to the total plant

\[ y_{D,k} = \frac{\dot{E}_{D,k}}{\dot{E}_{Cb,\text{tot}}} \] (3)

d) Exergy loss related to the fuel to the total plant

\[ y_{L,k} = \frac{\dot{E}_{L,k}}{\dot{E}_{Cb,\text{tot}}} \] (4)

¹ Dept. of Thermodynamics, University Politehnica of Bucharest.
where $\dot{E}_{\text{Ch} \to \text{f}} = \dot{E}_{\text{f}}$ is the exergy rate of the fuel to the total system.

e) The amortization rate of the invested capital cost $\dot{Z}_{\text{CI}}^k$, and the associated cost to operating and maintenance $\dot{Z}_{\text{OM}}^k$

$$\dot{Z}_k = \dot{Z}_{\text{OM}}^k + \dot{Z}_{\text{CI}}^k$$  \hfill (5)

f) The associated cost to exergy destruction

$$\dot{C}_{\text{D}, k} = c_{\text{Ch}, k} \cdot \dot{E}_{\text{D}, k}$$  \hfill (6)

where $c_{\text{Ch}, k}$ is the unitary cost of the fuel exergy.

g) Relative cost difference:

$$r_k = \frac{1 - \eta_{\text{ex}}}{\eta_{\text{ex}}} + \frac{\dot{C}_{\text{CI}}^k + \dot{Z}_{\text{OM}}^k}{c_{\text{Ch}, k} \cdot \dot{E}_{\text{P}, k}}$$  \hfill (7)

h) The exergoeconomic factor:

$$f_k = \frac{\dot{Z}_k}{\dot{Z}_k + \dot{C}_{\text{D}, k}}$$  \hfill (8)

3 Exergoeconomic Analysis - A Case Study

To show the special investigation and optimization abilities of the exergoeconomic analysis the scheme of a gas turbine system with air preheater and heat recovery generator has been chosen (fig.1). For such a system exergoeconomic correlations for the acquisition cost of the equipment are available. The two products are: the effective Power of the system $P_e=65$ MW and the Saturated steam 30 kg/s at pressure 20 bars.

The study of this cogeneration system accounts for the variation of the specific heat capacities with temperature and for the change in the composition of the thermal agent after combustion.

![Fig.1. Structure of the cogeneration system](image)

The objective function to be minimized is represented by the total cost of the product, cost composed by sum between the fuel rate cost and the capital investment amortization cost.

$$\dot{C}_T = \dot{C}_{\text{ch}} + \sum_{i=1}^{5} \dot{Z}_k$$  \hfill (9)

In the analysis of the considered system, five operating zones have been distinguished: compressor, combustion chamber, turbine, air preheater and the heat recovery steam generator (table 1).

To determine the unknown costs (per unit of exergy) auxiliary relationships are necessary. The construction of such relationships is based on two principles: principle F and P.

**Principle F:** If in a subsystem the fuel is represented as the difference between an incoming flux of exergy and an outgoing one the cost per unit of exergy corresponding to these fluxes remain constant.

**Principle P:** If a system or subsystem has several outgoing fluxes (products) simultaneously obtained, their unitary exergetic cost is the same.
4. Evaluation – thermoeconomic optimization

The direction of the optimum search is given by the values and evolution, from the optimization procedure, of the exergy zone destruction costs, of zone capital amortization costs, of zone exergetic efficiencies and of exergoeconomic costs. Based on the evolution of these parameters decisions will be taken regarding the sense and value of the change in the decisional parameters.

The methodology presented in this paper can be used in an exploratory approach and its aim is to minimize the cost of the considered system [1].

**First iteration:**

\( \frac{P_2}{P_1} = 10, \ \eta_{SC} = \eta_{ST} = 0.86, \ T_3 = 850K, \ T_4 = 1520K \)

1. Components are set in the decreasing order of the importance of their cost calculated as \( \dot{Z}_k + \dot{C}_{D,k} \) (table 3)
2. Design changes for components with large values for this sum are considered.
3. A peculiar attention is turned to components with a large relative exergetic cost difference \( r_k \) (eq. 6), especially when \( \dot{Z}_k \) and \( \dot{C}_{D,k} \) are large.
4. The exergoeconomic factor \( f_k \) (eq. 7) is used to identify the major source of cost (investment or exergy destruction cost).

By applying the presented stages one observes the following (figure 2): the combustion chamber, the turbine and the compressor have the largest values for the sum \( \dot{Z}_k + \dot{C}_{D,k} \); they are the most important components from the thermodynamic point of view.

**Combustion chamber (CA)** has a low value for the variable \( f \) (figure 3) which shows that the values for the associated costs are due near exclusively to the exergy destruction. Temperature \( T_4 \) is a key design variable, that influences the efficiency of the whole system and the investment costs of components.

Temperature \( T_3 \) is also a decisional variable because besides the combustion chamber it affect the exergy loss with current 7 as well as the performance and the investment cost of the air preheater and GRC.

An increase in these variables (\( T_3 \) and \( T_4 \)) reduce the value of \( \dot{C}_D \) for the combustion chamber and other components, but increases their investment capital cost (figures 12, 13, 14, 15).

For the **gas turbine (TG)**, the relative large value for factor \( f \) (figure 2) suggest that, the capital investment cost and the maintenance and operating cost are dominant. The capital investment cost of the turbine depends on temperature \( T_4 \), \( \frac{P_2}{P_1} \) and \( \eta_{ST} \). To reduce the high value \( \dot{Z}_T \), one should reduce at least one of these variables (figures 10, 12, 14).

**The compressor** has the largest value \( f \) and the second as measure \( r \) in the plant (figures 3 and 4). It is expected an improvement of the whole system cost if the value \( \dot{Z}_{CP} \) is reduced. That could be obtained by reducing the ratio \( \frac{P_2}{P_1} \) and \( \eta_{SC} \) (figures 6 and 8).
The Heat recovery generator (GRC) has the lowest exergetic efficiency and the largest value for \( r \) compared to other components (figures 4 and 5). The exergy destruction in the GRC may be reduced by the decrease in temperatures \( T_6 \) and \( T_7 \). Temperatures \( T_6 \) and \( T_7 \) could be reduced by the increase in \( T_3 \) and/or by reducing \( T_4 \) when keeping constant the remaining decisional variables (figures 13, 15).

The air preheater (PA) having a relative high value for \( f \) suggests to reduce the investment cost of this component. That can be achieved by reducing \( T_3 \) (figure 14).

As a sum of the previous conclusions, the following changes in the decision variables are expected to reduce the system cost.

Thus, in taking a decision for modifying, in a specific sense the values of ones of the decisional parameters, the dynamics of variation of the exergy destruction costs and of the investment amortization costs have been considered.

The above may be better observed if one presents the results of the sensibility studies of the zone exergy destruction and rate of amortization investment costs (see figures 6-14).

Fig. 12. Capital amortization cost at the variation of the temperature $T_4$ ($T_3=850 \, K$, $\eta_{SC}=\eta_{ST}=0.86$, $r_p=10$)

Fig. 13. Exergy destruction cost at the variation of the temperature $T_4$ ($T_3=850 \, K$, $\eta_{SC}=\eta_{ST}=0.86$, $r_p=10$)
Second iteration: The results of the exergoeconomic analysis corresponding to the second iteration from the optimum searching procedure are presented in table 4. Following the same way of reasoning the following changes in the decisional variables are proposed: the increase in temperature $T_3$ suggested by the evaluation of $CA$ and GRC; the decrease in $P_2/p_1$, $\eta_{SC}$ and $\eta_{ST}$ from the evaluation area of Cp and TG; the decrease in $T_4$ suggested by the evaluation of TG and GRC.

Values of the equipment acquisition costs and of the thermoeconomic variables Tabel 4.

The cost of the product of the global system: $C = 1.285$ €/s.
Additional iteration are necessary to get closer to the optimum solution. The values of the decisional variables that lead to optimum cost values are:

- $p_2/p_1 = 7.443$, $\eta_{SC} = 0.8254$, $\eta_{ST} = 0.8648$, $T_3 = 864K$, $T_4 = 1470K$

With these values the value of the objective function becomes $\dot{C}_{p,\text{tot}} = 1.173Eu/s$. The overall plant exergetic efficiency is over 38%.

5. Conclusions

The improve of the mathematical model has been done by achieving the exergoeconomic analysis of the plant as a whole and of each subsystem. This analysis gave the field of optimum decisional variables that correspond from both thermodynamic performances and cost with the acquisition and maintenance of the equipment.

An iterative method of cost minimization has been used which shows that exergy together with the exergoeconomic variables can be used for the minimization of the energetic system cost. After only a few iterations one reaches the optimum.
